# Description of the isotope chain ${ }^{180-196} \mathrm{Pt}$ within some solvable approaches 

A. A. Raduta ${ }^{a, b}$ and P. Buganu ${ }^{a}$<br>${ }^{\text {a) }}$ Department of Theoretical Physics, Institute of Physics and Nuclear Engineering, POBox MG6, Bucharest 077125, Romania and<br>${ }^{\text {b) }}$ Academy of Romanian Scientists, 54 Splaiul Independentei, Bucharest 050094, Romania

#### Abstract

Energies of the ground, $\beta$ and $\gamma$ bands as well as the associated $\mathrm{B}(\mathrm{E} 2)$ values are determined for each even-even isotope of the ${ }^{180-196} \mathrm{Pt}$ chain by the exact solutions of some differential equations which approximate the generalized Bohr-Mottelson Hamiltonian. The emerging approaches are called the Sextic and Spheroidal Approach (SSA), the Sextic and Mathieu Approach (SMA), the Infinite Square Well and Spheroidal Approach (ISWSA) and the Infinite Square Well and Mathieu Approach (ISWMA), respectively. While the first three methods were formulated in some earlier papers of the present authors, ISWMA is an inedit approach of this work. Numerical results are compared with those obtained with the so called $\mathrm{X}(5)$ and $\mathrm{Z}(5)$ models. A contour plot for the probability density as function of the intrinsic dynamic deformations is given for a few states of the three considered bands with the aim of evidencing the shape evolution along the isotope chain and pointing out possible shape coexistence.

PACS numbers: 21.10.Re, 21.60.Ev, 27.70.+q

## I. INTRODUCTION

Since the critical point symmetries [2-5] of the nuclear shape phase transitions were proposed, many experimental and theoretical efforts were made to find the nuclei described by the new symmetries. While at the beginning the $\mathrm{X}(5)$ [3] candidates were found in the mass region of $A \approx 150[6-8]$, recently a new region has been suggested for Os and Pt isotopes with $A \approx 180$ [9, 10]. In Refs. [11, 12] data for the isotopes ${ }^{176,178,180,188,190,192}$ Os were analyzed with the Sextic and Spheroidal Approach (SSA) [11], the Davidson and Spheroidal Approach (DSA) [12], the Infinite Square Well and Spheroidal Approach (ISWSA) [13] and the results were compared with those of the Coherent State Model (CSM) [14] and X(5). According to our analysis these isotopes present features for the $U(5) \rightarrow S U(3)$ shape phase transition with the critical point reached for ${ }^{176} \mathrm{Os}$ and ${ }^{188} \mathrm{Os}$. On the other hand, applying the Sextic and Mathieu Approach (SMA) [15] to ${ }^{188,190,192} \mathrm{Os}$, one points out that the isotope ${ }^{192} \mathrm{Os}$ is a good candidate for the critical point of the phase transition between the prolate and the oblate shapes through the triaxial shape corresponding to $\gamma_{0}=30^{\circ}$.

Encouraged by the results for the Os isotopes, we consider the above mentioned models also for the even-even ${ }^{180-196} \mathrm{Pt}$ isotopes. We aim not only at determining the energy spectra and the electric transition probabilities but also at showing the static deformation of each isotope in both the ground and excited states. New features like the shape coexistence or a transition from the prolate to oblate shapes through a triaxial deformation are expected to show up. Keeping in mind that the SMA, the ISWMA and the $\mathrm{Z}(5)$ [5] are suitable for the description of the triaxial nuclei lying close to $\gamma_{0}=30^{\circ}$, a comparison of their predictions represent a challenging task. ISWMA is the inedit model proposed in this paper.

Recently, in Ref. [10] it was shown that the isotope ${ }^{182} \mathrm{Pt}$ has some of the $\mathrm{X}(5)$ features. According to the Interacting Boson Model-1 (IBM-1) [16] and the General Collective Model [17] this isotope manifests shape coexistence and it is close to the critical point of the $U(5) \rightarrow S U(3)$ shape phase transition. Evidences for shape coexistence were also presented for ${ }^{176,178} \mathrm{Pt}[18,19],{ }^{184} \mathrm{Pt}[20],{ }^{186} \mathrm{Pt}[21]$ and ${ }^{188} \mathrm{Pt}$ [22], which suggests that this behavior is a specific feature for Pt isotopes. Some investigations where the ground state shape evolution in Pt isotope chain from the prolate towards the oblate shapes were performed in Refs. [23, 24].

The objectives formulated above are achieved according to the following plan. In Section

II, a short presentation of the formalisms used for the description of the Pt even-even isotopes is given. Numerical results and their comparison with the corresponding experimental data are discussed in Section III. The final conclusions are drawn in Section IV.

## II. SHORT PRESENTATION OF THE MODELS

The formalisms X(5), Z(5), ISWSA, ISWMA, SSA and SMA are derived by a set of approximations applied to the Bohr-Mottelson Hamiltonian [1],

$$
\begin{equation*}
H=-\frac{\hbar^{2}}{2 B}\left[\frac{1}{\beta^{4}} \frac{\partial}{\partial \beta} \beta^{4} \frac{\partial}{\partial \beta}+\frac{1}{\beta^{2} \sin 3 \gamma} \frac{\partial}{\partial \gamma} \sin 3 \gamma \frac{\partial}{\partial \gamma}-\frac{1}{4 \beta^{2}} \sum_{k=1}^{3} \frac{\hat{Q}_{k}^{2}}{\sin ^{2}\left(\gamma-\frac{2 \pi}{3} k\right)}\right]+C \frac{\beta^{2}}{2} \tag{2.1}
\end{equation*}
$$

amended with a potential $[25,26]$

$$
\begin{equation*}
V(\beta, \gamma)=V_{1}(\beta)+\frac{V_{2}(\gamma)}{\beta^{2}} \tag{2.2}
\end{equation*}
$$

The form of the $\beta$ and $\gamma$ potential allows to separate the $\beta$ variable from the $\gamma$ and the three Euler angles $\theta_{1}, \theta_{2}$ and $\theta_{3}$. Here, $\hat{Q}_{k}$ 's denote the angular momentum components in the intrinsic reference frame. A full separation may be however achieved by expanding the rotor term in power series of $\gamma$ around either of $\gamma_{0}=0$ or of $\gamma_{0}=\pi / 6$ and moreover by replacing the factor $\beta^{2}$ multiplying the $\gamma$-dependent term with its average value denoted hereafter by $\left\langle\beta^{2}\right\rangle$. The resulting equations are:

$$
\begin{gather*}
{\left[-\frac{1}{\beta^{4}} \frac{d}{d \beta} \beta^{4} \frac{d}{d \beta}+\frac{\Lambda}{\beta^{2}}+v_{1}(\beta)\right] f(\beta)=\varepsilon_{\beta} f(\beta)}  \tag{2.3}\\
{\left[-\frac{1}{\sin 3 \gamma} \frac{d}{d \gamma} \sin 3 \gamma \frac{d}{d \gamma}-W+v_{2}(\gamma)\right] \phi(\gamma)=\tilde{\varepsilon}_{\gamma} \phi(\gamma),} \tag{2.4}
\end{gather*}
$$

where the following notations are used:

$$
\begin{equation*}
v_{1}(\beta)=\frac{2 B}{\hbar^{2}} V_{1}(\beta), \quad v_{2}(\gamma)=\frac{2 B}{\hbar^{2}} V_{2}(\gamma), \quad \varepsilon_{\beta}=\frac{2 B}{\hbar^{2}} E_{\beta}, \quad \tilde{\varepsilon}_{\gamma}=\left\langle\beta^{2}\right\rangle \frac{2 B}{\hbar^{2}} E_{\gamma} \tag{2.5}
\end{equation*}
$$

$\Lambda$ and $W$ are the contributions coming from the rotor term and their expressions depend on the order of the $\gamma$ series truncation.

For the sake of fixing the notations and defining the main ingredients, in what follows the above mentioned approaches will be briefly described. For details we advise the reader to consult Refs. $[3,5,11-13,15,25,26]$. In Eq. (2.3), the X(5), Z(5), ISWSA and ISWMA models use a common potential in $\beta$, namely an infinite square well

$$
v_{1}(\beta)=\left\{\begin{array}{c}
0, \beta \leq \beta_{\omega}  \tag{2.6}\\
\infty, \beta>\beta_{\omega}
\end{array}\right.
$$

With such a choice Eq. (2.3) admits the Bessel functions of irrational order $\nu$, as solutions:

$$
\begin{equation*}
f_{s, L}(\beta)=C_{s, L} \beta^{-\frac{3}{2}} J_{\nu}\left(\frac{x_{s, L}}{\beta_{\omega}} \beta\right), \quad s=1,2,3, \ldots \tag{2.7}
\end{equation*}
$$

$C_{s, L}$ denotes the normalization factor, $x_{s, L}$ the Bessel function zeros, while $L$ is the total intrinsic angular momentum.

By contrast the SSA and SMA, use in Eq. (2.3) a sextic oscillator plus a centrifugal barrier potential [27],

$$
\begin{equation*}
v_{1}^{ \pm}(\beta)=\left(b^{2}-4 a c^{ \pm}\right) \beta^{2}+2 a b \beta^{4}+a^{2} \beta^{6}+u_{0}^{ \pm}, c^{ \pm}=\frac{L}{2}+\frac{5}{4}+M, M=0,1,2, \ldots \tag{2.8}
\end{equation*}
$$

Here, $c^{ \pm}$has two different values, one for $L$ even and other for $L$ odd, while $u_{0}^{ \pm}$are constants which are fixed such that the two potentials $v_{1}^{+}$and $v_{1}^{-}$have the same minimum energy. Eq. (2.3), with $\Lambda=L(L+1)-2$ and the potential given by Eq. (2.8), is quasi-exactly solved, the solutions being of the form:

$$
\begin{equation*}
\varphi_{n_{\beta}, L}^{(M)}(\beta)=N_{n_{\beta}, L} P_{n_{\beta}, L}^{(M)}\left(\beta^{2}\right) \beta^{L+1} e^{-\frac{a}{4} \beta^{4}-\frac{b}{2} \beta^{2}}, \quad n_{\beta}=0,1,2, \ldots M, \tag{2.9}
\end{equation*}
$$

where $N_{n_{\beta}, L}$ is the normalization factor, while $P_{n_{\beta}, L}^{(M)}\left(\beta^{2}\right)$ are polynomials of order $n_{\beta}$ in $\beta^{2}$.
Concerning the Eq. (2.4), the $\mathrm{X}(5)$ and $\mathrm{Z}(5)$ chose an oscillator and a shifted oscillator potential, respectively:

$$
\begin{equation*}
v_{2}(\gamma)=c \frac{1}{2}\left(\gamma-\gamma_{0}\right)^{2} \tag{2.10}
\end{equation*}
$$

Indeed $\gamma_{0}=0$, for $\mathrm{X}(5)$, and $\gamma_{0}=\pi / 6$ for $\mathrm{Z}(5)$. The solutions of Eq. (2.4) are the generalized Laguerre polynomials, $L_{n}^{m}$, if $\gamma_{0}=0$

$$
\begin{equation*}
\eta_{n_{\gamma}, K}(\gamma)=C_{n, K} \gamma^{|K / 2|} e^{-(3 a) \gamma^{2} / 2} L_{n}^{|K|}\left(3 a \gamma^{2}\right), n=\left(\frac{n_{\gamma}-|K|}{2}\right), a=\frac{\sqrt{c}}{3}, \quad n_{\gamma}=0,1,2, \ldots \tag{2.11}
\end{equation*}
$$

The quantum number K corresponds to the angular momentum projection on the intrinsic z-axis. and the Hermite polynomials $H_{n}$, for $\gamma_{0}=\pi / 6$

$$
\begin{equation*}
\eta_{\bar{n}_{\gamma}}=N_{\bar{n}_{\gamma}} H_{\bar{n}_{\gamma}}(b(\gamma-\pi / 6)) e^{-b^{2}(\gamma-\pi / 6) / 2}, b=\left(\frac{c\left\langle\beta^{2}\right\rangle}{2}\right)^{1 / 4}, \bar{n}_{\gamma}=0,1,2, \ldots, \tag{2.12}
\end{equation*}
$$

Both models, the $\mathrm{X}(5)$ and the $\mathrm{Z}(5)$, consider in Eq. (2.4) a zeroth order of approximation for the rotor term.

This is not the case for the ISWSA, ISWMA, SSA and SMA models, where a second order power expansion of both the the rotor term and the periodic potential

$$
\begin{equation*}
v_{2}(\gamma)=u_{1} \cos 3 \gamma+u_{2} \cos ^{2} 3 \gamma \tag{2.13}
\end{equation*}
$$

is used, which results of having the spheroidal $\left(S_{m, n}\right)$ and Mathieu $\left(\mathcal{M}_{n}\right)$ functions as solutions of the resulting differential equations, respectively:

$$
\begin{equation*}
\eta(\gamma)=S_{m, n}(\cos 3 \gamma ; c), \eta(\gamma)=\frac{\mathcal{M}_{n}(3 \gamma ; q)}{\sqrt{|\sin 3 \gamma|}} \tag{2.14}
\end{equation*}
$$

The expressions of $c$ and $q$ will be specified below.
The advantages of the Mathieu and spheroidal functions consist of that they are periodic, defined on a bound interval and normalized to unity with the integration measure of $|\sin 3 \gamma| d \gamma$, preserving in this way the hermiticity of the initial Hamiltonian. Note that the other approaches do not satisfy these conditions.

The total energy of the system is obtained by summing the eigenvalues of the $\beta$ and $\gamma$ equations:

$$
\begin{equation*}
\varepsilon=\varepsilon_{\beta}+\tilde{\varepsilon}_{\gamma} . \tag{2.15}
\end{equation*}
$$

The excitation energies yielded by the formalisms used in the present paper, are as follows:

$$
\begin{equation*}
\mathbf{X}(5): E\left(s, L, n_{\gamma}, K\right)-E(1,0,0,0)=B_{1}\left(x_{s, L}^{2}-x_{1,0}^{2}\right)+\delta_{K, 2} X, \quad X=A_{1}+4 C_{1} \tag{2.16}
\end{equation*}
$$

with $A_{1}, B_{1}$ and $C_{1}$ arbitrary parameters. In our calcultions the parameter $X$ is fitted.

$$
\begin{equation*}
\mathbf{Z}(5): E\left(s, L, n_{\gamma}=0, R\right)-E(1,0,0,0)=B_{1}\left(x_{s, L, R}^{2}-x_{1,0,0}^{2}\right), B_{1}=\frac{1}{\beta_{\omega}^{2}} \frac{\hbar^{2}}{2 B} \tag{2.17}
\end{equation*}
$$

ISWSA: $\quad E\left(s, n_{\gamma}, m_{\gamma}, L, K\right)=B_{1} x_{s, L}^{2}+F\left[9 \lambda_{m_{\gamma}, n_{\gamma}}(c)+\frac{u_{1}}{2}+\frac{11}{27} D-\frac{L(L+1)}{3}\right]$,

$$
\begin{align*}
& \lambda_{m_{\gamma}, n_{\gamma}}=\frac{1}{9}\left[\tilde{\varepsilon}_{\gamma}-\frac{u_{1}}{2}-\frac{11}{27} D+\frac{1}{3} L(L+1)\right], c^{2}=\frac{1}{9}\left(\frac{u_{1}}{2}+u_{2}-\frac{2}{27} D\right) \\
& m_{\gamma}=\frac{K}{2}, \quad D=L(L+1)-K^{2}-2, F=\frac{1}{\left\langle\beta^{2}\right\rangle} \frac{\hbar^{2}}{2 B} \tag{2.18}
\end{align*}
$$

ISWMA: $\quad E\left(s, n_{\gamma}, L, R\right)=B_{1} x_{s, L}^{2}+F\left[9 a_{n_{\gamma}}(L, R)+18 q(L, R)-\frac{3}{4} R^{2}-\frac{5}{2}\right]$,

$$
\begin{equation*}
q=\frac{1}{36}\left(\frac{10}{9} L(L+1)-\frac{13}{12} R^{2}+u_{1}-\frac{9}{4}\right), a_{n_{\gamma}}=\frac{1}{9}\left(\tilde{\varepsilon}_{\gamma}+\frac{3}{4} R^{2}+\frac{5}{2}\right)-2 q \tag{2.19}
\end{equation*}
$$

SSA:
$E\left(n_{\beta}, n_{\gamma}, m_{\gamma}, L, K\right)=E\left[b(2 L+3)+\lambda_{n_{\beta}}^{(M)}+u_{0}^{ \pm}\right]+F\left[9 \lambda_{m_{\beta}, n_{\gamma}}(c)+\frac{u_{1}}{2}+\frac{11}{27} D-L(L+1)\right]$,
$\lambda_{m_{\gamma}, n_{\gamma}}=\frac{1}{9}\left[\tilde{\varepsilon}_{\gamma}-\frac{u_{1}}{2}-\frac{11}{27} D+\frac{1}{3} L(L+1)\right]+\frac{2 L(L+1)}{27}, E=\frac{\hbar^{2}}{2 B}$,

$$
\begin{equation*}
E\left(n_{\beta}, n_{\gamma}, L, R\right)=E\left[4 b s(L)+\lambda_{n_{\beta}}^{(M)}(L)+u_{0}^{\pi}\right]+F\left[9 a_{n_{\gamma}}(L, R)+18 q(L, R)-\frac{3}{4} R^{2}-\frac{5}{2}\right], \tag{2.21}
\end{equation*}
$$

where $\lambda_{n_{\beta}}^{(M)}(L)$ satisfy the equation:

$$
\begin{equation*}
\left[-\left(\frac{d^{2}}{d \beta^{2}}+\frac{4 s-1}{\beta} \frac{d}{d \beta}\right)+2 b \beta \frac{d}{d \beta}+2 a \beta^{2}\left(\beta \frac{d}{d \beta}-2 M\right)\right] P_{n_{\beta}, L}^{(M)}\left(\beta^{2}\right)=\lambda_{n_{\beta}}^{(M)} P_{n_{\beta}, L}^{(M)}\left(\beta^{2}\right) . \tag{2.22}
\end{equation*}
$$

The reduced E2 transition probabilities for ISWSA and SSA are determined with the reduced matrix element of the transition operator:
$T_{2 \mu}^{(E 2)}=t_{1} \beta\left[\cos \gamma D_{\mu 0}^{2}+\frac{\sin \gamma}{\sqrt{2}}\left(D_{\mu 2}^{2}+D_{\mu,-2}^{2}\right)\right]+t_{2} \sqrt{\frac{2}{7}} \beta^{2}\left[-\cos 2 \gamma D_{\mu 0}^{2}+\frac{\sin 2 \gamma}{\sqrt{2}}\left(D_{\mu 2}^{2}+D_{\mu,-2}^{2}\right)\right]$,
between the corresponding initial $\left|L_{i} M_{i}\right\rangle$ and final $\left|L_{f} M_{f}\right\rangle$ states, as described above:

$$
\begin{equation*}
B\left(E 2 ; L_{i} \rightarrow L_{f}\right)=\left|\left\langle L_{i}\left\|T_{2}^{(E 2)}\right\| L_{f}\right\rangle\right|^{2} \tag{2.24}
\end{equation*}
$$

Here the Rose's convention [28] was used for the reduced matrix elements. For SMA, ISWMA and $Z(5)$, in the expression of the transition operator (2.23) $\gamma$ is substituted with $\gamma-2 \pi / 3$. The argument is justified by the fact that $\gamma-2 \pi / 3$ defines the axis 1 of the principal inertial ellipsoid. Indeed, the transformation from the laboratory to the intrinsic frame is a rotation defined by the matrix $D_{M R}^{L}$, where M and R are eigenvalues of the operator $\hat{Q}_{1}$. The $\mathrm{X}(5)$ and $\mathrm{Z}(5)$ models keep only the zero order approximation of the first $\gamma$-term in the transition operator (2.23).

## III. NUMERICAL RESULTS

The formalisms presented in Section II were applied to some even-even isotopes of Pt: ${ }^{180-196} \mathrm{Pt}$. It is commonly accepted that nuclear spectra can be classified by the values of the energy ratios:

$$
\begin{align*}
R_{4_{g}^{+} / 2_{g}^{+}} & =\frac{E_{4_{g}^{+}}-E_{0_{g}^{+}}}{E_{2_{g}^{+}}-E_{0_{g}^{+}}}, \\
R_{0_{\beta}^{+} / 2_{g}^{+}} & =\frac{E_{0_{\beta}^{+}}-E_{0_{g}^{+}}}{E_{2_{g}^{+}}-E_{0_{g}^{+}}^{+}} . \tag{3.1}
\end{align*}
$$

Moreover, it seems that nuclei satisfying a certain symmetry are characterized by almost constant ratios. The values of these ratios associated to the isotopes considered here are
collected in Table I. As seen from there, the ratios $R_{4_{g}^{+} / 2_{g}^{+}}$for ${ }^{180,182,184} \mathrm{Pt}$ are close to that predicted by the $X(5)$ approach. By contrast the other ratio $R_{0_{\beta}^{+} / 2_{g}^{+}}$indicates that these isotopes are far from the ideal picture of $X(5)$. As a matter of fact this feature is consistent with the results of Ref.[29] saying that not all nuclear properties reach the critical point in a phase transition in the same isotope. We apply the approaches ISWSA and SSA to the mentioned isotopes in order to test their ability to account for these complementary features.

Concerning the description called $Z(5)$ this is appropriate for ${ }^{190,192,194,196} \mathrm{Pt}$, the statement being supported by the values of both ratios. Indeed, the detailed numerical analysis of Ref.[5] shows a good agreement between calculations and experimental data. In this context the application of the ISWMA and SMA to these isotopes will provide a sensible comparison of the formalisms on one hand and the $Z(5)$ on the other hand.

It is well known that the triaxial rigid rotor (TRR) predicts [30] a relation between the first three excited state energies:

$$
\begin{equation*}
\triangle E \equiv E_{3_{\gamma}^{+}}-E_{2_{\gamma}^{+}}-E_{2_{g}^{+}}=0 . \tag{3.2}
\end{equation*}
$$

Due to this fact the above equation is considered to be a signature for a triaxial deformation of $\gamma_{0}=30^{0}$. For the isotope ${ }^{192} \mathrm{Pt}$ the above equation reads: $|\Delta E|=8 \mathrm{keV}$, which means that the mentioned isotope is close to the ideal triaxial rigid rotor. Considering this isotope among the treated isotopes allows us to answer the question whether these approaches are suitable for the description of the triaxial nuclei. The isotopes ${ }^{186,188,190,192,194,196} \mathrm{Pt}$ may be considered to be $\gamma$-unstable nuclei, having the ratio $R_{4_{g}^{+} / 2_{g}^{+}}$close to 2.5 . A special case is that of ${ }^{186} \mathrm{Pt}$ which has the had state of gamma band higher in energy than the first beta state which result in claiming a gamma stable picture. Most likely this nucleus exhibits the main features for the critical point of the phase transition from prolate to oblate shapes. Due to the specific structure of their potentials in the $\gamma$ variable, the ISWSA and SSA seem to be suitable to describe both the $\gamma$-unstable and $\gamma$-stable deformed nuclei. Actually this argument justifies including ${ }^{186} \mathrm{Pt}$ and ${ }^{188} \mathrm{Pt}$ on the list of considered isotopes.

Each approach involves a number of free parameters for energies as well as for $\mathrm{B}(\mathrm{E} 2)$ values. These are fixed by fitting some particular experimental data concerning either the excitation energies or the reduced transition probabilities. The results of the fitting procedure adopted are listed in Tables II-VII.

for the quadrupole electric transitions between states of these bands are compared with the corresponding experimental data in Tables VIII-X and XI-XIII, respectively. For each formalism the agreement between the calculation results and the corresponding experimental data is quantitatively appraised by the r.m.s values of the deviations.

From Table VIII, one can see that spectra of the isotopes ${ }^{180} \mathrm{Pt},{ }^{182} \mathrm{Pt}$ and ${ }^{184} \mathrm{Pt}$ are better described by SSA and ISWSA than by X(5). The best approach seems to be SSA. Moreover, the $\mathrm{X}(5)$ failure in explaining the data from the $\beta$ band is removed by SSA, and that happens especially for ${ }^{182} \mathrm{Pt}$. Concerning the $\gamma$ band, all three formalisms, SSA, ISWSA

and $\mathrm{X}(5)$, encounter difficulties in explaining the band had energy. A possible explanation would be that the state $2_{\gamma}^{+}$, does not actually belong to the $\gamma$ band. A similar situation is met in ${ }^{186} \mathrm{Pt}$. In ${ }^{188} \mathrm{Pt}$, however, all three bands considered here are realistically described by SSA.

The comparison of the numerical results yielded by SMA, ISWMA and $Z(5)$ with experimental data for the even-even isotopes ${ }^{190-196} \mathrm{Pt}$, is made in Tables IX and X, with the

TABLE VII: The same as in Table V, but for the SMA model.

result in favor of SMA and ISWMA.
The electromagnetic transition probabilities, calculated with Eq. (2.24), are included in Tables XI-XIII. Analyzing the r.m.s. values for each model, one may conclude that SSA and ISWSA describe the experimental data batter than X(5), while SMA and ISWMA better than $Z(5)$. An explanation for this picture could be that $X(5)$ and $Z(5)$ use only the zero order approximation of the harmonic part of the transition operator (2.23). Indeed, as shown in Table XI, for ${ }^{180} \mathrm{Pt}$ the results obtained by SSA and ISWSA using only the harmonic transition operator are almost identical with those of $\mathrm{X}(5)$. By contrast for ${ }^{182,184} \mathrm{Pt}$ where the anharmonic contributions were included, the results of SSA and ISWSA are better than those of $\mathrm{X}(5)$. It is worth noticing that the r.m.s. associated to $\mathrm{Z}(5)$ for ${ }^{192} \mathrm{Pt}$ and ${ }^{196} \mathrm{Pt}$ are smaller than those provided by ISWMA. This situation might be caused by the fact the two approached considered for the $\gamma$ band different descriptions. Indeed, in the framework of $\mathrm{Z}(5)$ the states of $\gamma$ band are characterized by $n_{\gamma}=0$ while the ISWMA $\gamma$ states have $n_{\gamma}=1$.

TABLE VIII: Excitation energies, given in units of keV , of the ground, $\beta$ and $\gamma$ bands states $\mathrm{J}_{i}^{+}$ with $i=g, \beta, \gamma$, for ${ }^{180,182,184} \mathrm{Pt}$ yielded by the SSA, ISWSA and $\mathrm{X}(5)$ approaches, are compared with the corresponding experimental data taken from Refs. [31-33].

In Table XIV we list the results for branching ratios of few states from the $\gamma$ and $\beta$ bands obtained by SSA, ISWSA, SMA and ISWMA approaches, respectively. They are compared with the experimental data of Ref.[40]. For ${ }^{190,192,194} \mathrm{Pt}$ we list also the results yielded by the $\mathrm{Z}(5)$ formalism. The prameters detemining the transition operator were fixed as follows. For ${ }^{188} \mathrm{Pt}$ and ${ }^{190} \mathrm{Pt}$ we kept $t_{1}$ as given in Table IV and VI respectively, while $t_{2}$ was fixed by a least square procedure. The results for $t_{2}$ are also listed in Table XIV. As for the rest of isotopes from above mentioned Table, the parameters $t_{1}$ and $t_{2}$ are as listed in Table VI.

Another objective of the present work is to determine the shape of each considered isotope in ground and excited states, within both the SSA and the SMA. Indeed, it is interesting to see how the shape changes when one passes from one isotope to another and moreover whether this picture is state dependent.We expect to visualize the shape phase transition and also possible shape coexistence. The static shape is defined by the values of the intrinsic variables $\beta$ and $\gamma$ for which the probability density (the probability in the volume unit of $d \beta d \gamma)$,

$$
\begin{equation*}
P(\beta, \gamma)=|f(\beta) \phi(\gamma)|^{2} \beta^{4}|\sin 3 \gamma| \tag{3.3}
\end{equation*}
$$

reaches a maximum value. In Figs. 1-3, the contour plots are represented in the coordinates $(\beta \cos \gamma, \beta \sin \gamma)$. In order to save the space we chose two representatives for $\mathrm{SSA},{ }^{180} \mathrm{Pt}$ and
${ }^{188} \mathrm{Pt}$, and one for SMA, ${ }^{190} \mathrm{Pt}$. Indeed, the graphs corresponding to ${ }^{182-186} \mathrm{Pt}$ are similar to that of ${ }^{180} \mathrm{Pt}$ and those of ${ }^{192-196} \mathrm{Pt}$ resemble that of ${ }^{190} \mathrm{Pt}$. We may ask ourself why to make such plots once we know that the power expansion in $\gamma$ was performed around $\gamma=0^{0}$ and $\gamma=30^{\circ}$. We notice that the density maxima are met not in the same point where the potential is minimum. The reason is that the density accounts also for the kinetic energy and moreover includes a factor defining the measure of the integration in the $\beta$ and $\gamma$ coordinates. These figures reflect the structure of the wave functions. Indeed, since the $\gamma$ dependent function depends on $\cos 3 \gamma$ and the spheroidal functions are symmetric with respect to the space reflection transformation, the graphs exhibit the symmetry $\gamma \rightarrow \pi / 3-\gamma$. Concerning SMA the mentioned symmetry is caused by the fact the potential in $\gamma$ is function of $\cos ^{2} 3 \gamma$. Also, the node of the $\beta$ function causes a doublet maxima with the same $\gamma$. For ${ }^{188} \mathrm{Pt}$ we notice equal density curves which surround two maxima of identical beta. This situation is specific to the phase coexistence. It is worth mentioning that such transition is showing up despite the fact the for all isotopes ${ }^{180-188} \mathrm{Pt}$ we used a power expansion in $\gamma$ around $0^{0}$. That means that the transition is caused not only by the potential shape but also by the structure coefficients involved in the associated differential equations. Actually we calculated the spectroscopic properties of Pt isotopes with $A \geq 190$ also with a power expansion in $\gamma$ around $\gamma=0$. However, the results of SMA are characterized by a smaller r.m.s values for the deviations of the predictions from the experimental data. It is interesting to note that although we changed the description when we passed from ${ }^{188} \mathrm{Pt}$ to ${ }^{190} \mathrm{Pt}$ the probability density undergoes a smooth transition. The maxima surrounded by equidensity curves merge in one maximum at $\gamma=30^{\circ}$ for ground and $\beta$ band states while for $\gamma$ band states the doublets are well separated. How this picture is modified when additional degrees of freedom like octupole [41, 42] or single particle [43, 44] will be analyzed elsewhere.

FIG. 1: (Color online) Probability densities for the states $0_{g}^{+}, 10_{g}^{+}, 0_{\beta}, 10_{\beta}, 2_{\gamma}^{+}, 3_{\gamma}^{+}, 9_{\gamma}^{+}$and $10_{\gamma}^{+}$of ${ }^{180} \mathrm{Pt}$ calculated with SSA.

FIG. 2: (Color online)The same as in Fig. 1 but for ${ }^{188} \mathrm{Pt}$.

FIG. 3: (Color online) Probability densities for the states $0_{g}^{+}, 10_{g}^{+}, 0_{\beta}, 8_{\beta}, 2_{\gamma}^{+}, 3_{\gamma}^{+}, 9_{\gamma}^{+}$and $10_{\gamma}^{+}$of ${ }^{190} \mathrm{Pt}$ calculated with SMA.

## IV. CONCLUSIONS

In the previous Section we described some even-even isotopes of Pt by four solvable models emerging from the generalized Bohr Mottelson Hamiltonian. Indeed for the isotopes with $180 \leq A \leq 188$ the approaches are those abbreviated by SSA and ISWSA, respectively, while for the rest of nuclei, $190 \leq A \leq 196$ the SMA and ISWMA are alternatively used. It is worth mentioning that the approach called ISWMA was used for the first time in the present paper. Since the first set exhibits some features of the $X(5)$ "symmetry" we compared the results of our calculations with those obtained with the $\mathrm{X}(5)$ formalism, if they are available. As for the other isotopes the results were compared with the $Z(5)$ results. One concludes that our results are slightly better than those obtained with $\mathrm{X}(5)$ and $\mathrm{Z}(5)$ methods regarding both the excitation energies and reduced transition E2 probabilities.

The wave function structure is nicely reflected in the contour plots for the probability density. It is suggested that due to the Hamiltonian symmetries the wave functions might be suitable for accounting for shape evolution as well as for possible shape coexistence.
